

JavaScript: how to implement the jQuery one() method

It's not difficult in JavaScript to make an event fire just once.

jQuery provides us with the one() method. Here's our implementation:

```
'use strict';

const one = ( element, evtName, callback ) => {

  element.addEventListener( evtName, e => {
    e.preventDefault();
    if( !element.dataset.fired ) {
      callback();
      element.dataset.fired = true;
    }
  }, false);
};
```

Through a simple boolean flag we can execute our code just once on a given element.
